

# Geometrical Language Description

# CONTENTS

<b>INRODUCTION .....</b>	<b>2-5</b>
Designation and area of appliance .....	2-5
Measurement units .....	2-5
Definitions, applicable in the language .....	2-6
Parameterization of geometrical objects.....	2-6
<b>1 DEFINITION OPERATORS OF GEOMETRICAL ELEMENTS..</b>	<b>2-7</b>
<b>1.1 COMMON REGULATIONS .....</b>	<b>2-7</b>
1.1.1 Creation of an operator,types of geometrical variables.....	2-7
1.1.2 Directions of lines and circles.....	2-8
1.1.3 Assignment of a coordinate system .....	2-8
<b>1.2 POINT ASSIGNMENT .....</b>	<b>2-11</b>
1.2.1 Point assignment by rectangular coordinates .....	2-11
1.2.2 Point assignment by polar coordinates .....	2-12
1.2.3 Point assignment by increment of coordinates relatively the earlier defined point .....	2-13
1.2.5 Point, defined by polar coordinates relatively the earlier defined point .....	2-14
1.2.6 Point, as the center of the earlier defined circle .....	2-14
1.2.7 Point assignment by intersection of a line and a circle .....	2-15
1.2.9 Assignment of a point of the axial symmetry .....	2-16
1.2.10 Point assignment by transition to a new coordinate system .....	2-17
1.2.11 Point assignment, lying on a circle under the defined central angle .....	2-18
1.2.12 Point, defined by one of coordinates and lying on a line .....	2-19
1.2.13 Assignment of a point, lying on a line at distance from the earlier defined point .....	2-20
1.2.14 Point, as the nodal point of a contour .....	2-20
1.2.15 Point, defined by intersection of a line and a contour .....	2-20
1.2.16 Point, defined by intersection of a circle and a contour .....	2-21
1.2.17 Point, defined by intersection of two contours .....	2-22
1.2.19 Touch point of two contours in transition of one of them towards the indicated direction until collision with the second .....	2-23
1.2.20 Point, laying on a contour at the indicated distance along a contour from the earlier defined point .....	2-23
1.2.21 Point scaling .....	2-23
1.2.22 Projection of a point on a circle.....	2-24
<b>1.3 LINE ASSIGNMENT .....</b>	<b>2-25</b>
1.3.1 Line passing through two points defined earlier .....	2-25
1.3.2 Line passing through a point under the defined angle .....	2-25
1.3.3 Line passing through a point, tangent to the defined circle .....	2-26
1.3.4 Line tangent to a circle under the defined angle .....	2-27
1.3.5 Assignment of a line tangent to two circles .....	2-27
1.3.6 Assignment of a line parallel to the given one .....	2-28
1.3.7 Line tangent to a contour under the defined angle.....	2-29
1.3.8 Line passing through a point and tangent to a contour .....	2-30
1.3.9 Line as an element of the earlier defined contour .....	2-30
1.3.10 Line defined by coefficients of a normal equation of a line .....	2-31
1.3.11 Transition of a line .....	2-31
1.3.12 Rotation of a line around a point to the defined angle .....	2-31

1.3.13 Line scaling .....	2-31
<b>1.4 CIRCLE ASSIGNMENT .....</b>	<b>2-33</b>
1.4.1 Circle, defined by a center and a radius .....	2-33
1.4.2 Circle, symmetrical to the initial circle relatively a line .....	2-34
1.4.3 Circle, defined by displacement of the initial circle .....	2-34
1.4.4 Circle with the defined center, tangent to a line .....	2-35
1.4.5 Circle with the defined center, tangent to another circle .....	2-35
1.4.6 Circle of the defined radius, tangent to two lines .....	2-36
1.4.7 Circle of the defined radius, tangent to two circles .....	2-36
1.4.8 Circle of the defined radius, tangent to the earlier defined line and circle .....	2-37
1.4.9 Circle of the defined radius, passing through a point and tangent to a line .....	2-38
1.4.10 Circle of the defined radius, passing through a point and tangent to a circle .....	2-38
1.4.11 Circle of the defined radius, passing through two points .....	2-39
1.4.12 Circle, concentric to the present circle .....	2-40
1.4.13 Circle with a center in the defined point and tangent to a contour .....	2-40
1.4.14 Circle, as an element of the earlier defined contour .....	2-41
1.4.15 Rotation of a circle around a point to the defined angle .....	2-41
1.4.16 Circle scaling .....	2-41
<b>1.5 CIRCLE, DEFINED FROM THE CONDITION OF THREE CONTACTS .....</b>	<b>2-43</b>
1.5.1 Circle, passing through two points and tangent to the present circle .....	2-43
1.5.2 Circle, passing through two points and tangent to the present line .....	2-44
1.5.3 Circle, passing through one point and tangent to two lines .....	2-44
1.5.4 Circle, passing through one point and tangent to two circles .....	2-45
1.5.5 Circle, passing through one point and tangent to a line and a circle .....	2-45
1.5.6 Circle, tangent to two circles and a line .....	2-46
1.5.7 Circle, tangent to two lines and a circle .....	2-46
1.5.8 Circle, passing through three points .....	2-47
1.5.9 Circle, tangent to three lines .....	2-47
1.5.10 Circle, tangent to three circles .....	2-48
<b>1.6 CONTOUR .....</b>	<b>2-49</b>
1.6.1 Conception of a contour .....	2-49
1.6.2 Formation of a contour from the defined geometrical elements .....	2-49
1.6.3 Rounding radius .....	2-50
<b>1.7 CONTOUR, DEFINED BY MULTITUDE OF POINTS .....</b>	<b>2-51</b>
1.7.1 Contour – broken line .....	2-51
1.7.2 Spline .....	2-51
1.7.3 Approximation by arcs .....	2-52
1.7.4 Spiral of Archimed .....	2-52
<b>1.8 MODIFICATION OF A CONTOUR .....</b>	<b>2-53</b>
1.8.1 Parallel transfer .....	2-53
1.8.2 Transfer – rotation .....	2-54
1.8.4 Transfer of a contour to the relative coordinate system .....	2-55
1.8.4 Assignment of a contour by the axial symmetry .....	2-56
1.8.5 Creation of an equidistant contour .....	2-57
1.8.6 Multiple rotation with joining .....	2-57
1.8.7 Multiple transfer with joining .....	2-58

1.8.8 Contour defined by transfer of the initial contour to the defined direction  
 up to the collision with another one ..... 2-58

1.8.9 Change of a direction of rounding ..... 2-59

1.8.10 Joining of contours ..... 2-59

1.8.11 Contour defined by scaling of the initial contour ..... 2-59

1.8.12 Selection of a contour, as a sub-multitude of the initial contour ..... 2-60

1.8.13 Rounding in the nodal point of the initial contour ..... 2-60

**1.9 GEOMETRICAL FUNCTIONS ..... 2-61**

1.9.1 Functions of transformation of geometrical elements parameters into  
 the real data types ..... 2-61

1.9.2 Functions of transformation of geometrical elements` mutual location  
 parameters into the real data types ..... 2-61

1.9.3 Functions of calculation of the ortogonal distance between two points  
 by axes "X" and "Y" ..... 2-62

# INTRODUCTION

---

## Designation and area of appliance

Geometrical processor is designed to execute geometrical calculations, concerned with determination of geometrical objects on a plane, calculation of parameters of their mutual location and modifications of these objects. The language of the geometrical processor is used in the planar creation mode. The geometrical processor operates with the following data types:

- Point
- Straight Line (hereinafter referred to as LINE)
- Circle
- Contour
- Coordinate system

The presence of the listed data types allows operating with geometrical definitions.

Geometrical processor can be used in solution of a wide range of problems, concerned with geometrical calculations.

---

## Measurement units

In the language of monitor, it is common to define:

- Linear measurements in millimeters
- Angles in degrees, with decimal portions, i.e. decimal number.

An angle is positive, if counted out from the positive direction of the "X" axis counter-clockwise. An angle is negative, if counted out from the positive direction of the "X" axis clockwise.

**Definitions, applicable in the language**

Identifiers of types of geometrical objects have the following designations:

- O1, O2, O3...On - coordinate systems;
- O1, P2, P3...Pn - points;
- L1, L2, L3...Ln - line lines;
- LX, LY - coordinate axes of the initial system;
- C1, C2, C3...Cn - circles;
- K1, K2, K3...Kn - contours.

Identifiers of geometrical functions have the following designations:

- X, Y- coordinates;
- A – angle;
- M - distance;
- R – radius;
- D – diameter;
- N – number or amount.

When writing operators the difference between capital and small letters does not matter.

---

**Parameterization of geometrical objects**

In any operator of geometrical language instead of any numerical value, a variable or an arithmetical expression can be used.

At that, the variable separates from an identifier by a blank space or a dot. An arithmetical expression encloses in oval brackets.

# 1 DEFINITION OPERATORS OF GEOMETRICAL ELEMENTS

## 1.1 COMMON REGULATIONS

### 1.1.1 Creation of an operator, types of geometrical variables

Assignment of geometrical elements in the language is performed by means of calculation operators and giving value to variables of “point”, “line”, “circle”, “coordinate system” types. In the left part of the operator there is a variable which identifies a being assigned geometrical object, and in the right part – one of multitude of acceptable methods of the object’s definition. By a type of a variable defines its possible values, operations of the variable definition, and its use. There is a strict mnemonic connection between the type of a variable and its designation. For instance, all variables of “line” type have designation “L” with an identification number. Therefore, designations of variables are included into the Language dictionary and are the subordinate words.

In common view the operator of a geometrical object assignment has the following format:

---

*Identifier of a type with a number = a list of parameters in the assignment method format.*

---

or

---

*Identifier of a type with a number [a list of parameters in the assignment method format].*

---

The parameters can be geometrical functions, identifiers of earlier defined geometrical elements or enclosed operators of geometrical element assignment. Formats of assignment methods are described in the present topic. If a method of assignment envisages indication of coordinates by two axes, then it is possible to omit identifiers “X” and “Y”. At that, the first number is interpreted as a coordinate on the “X” axis, and the second, as a coordinate on the “Y” axis.

If an element is used in assignment of a contour or another element, it can be re-defined, by assigning a new element with similar identifier. Exploitation and re-definition within one operator is acceptable.

Example:

$$L20=L20, M50$$

### 1.1.2 Directions of lines and circles

Being defined geometrical elements as default locate in the horizontal plane "XOY". Assignment is performed in the right rectangular coordinate system.

Positive direction of a line is defined in its assigning, and do not change further. For instance, if a line is defined by two points, then positive is direction from the first point to the second; and if a line is defined as parallel to the earlier defined one, then positive directions of the lines coincide.

Positive direction of a line is the direction counter-clockwise. All defined circles has positive direction independently from their direction when were defined.

### 1.1.3 Assignment of a coordinate system

The initial coordinate system accepts as default and is primary. All assigned coordinate systems are relative and lie in the initial. Parameters of all geometrical elements, being defined in the relative system, automatically recalculates in the primary coordinate system

- **Assignment of a new system by coordinates of a center and the rotation angle relatively the primal system.**

Format:

$$O_i = X_x, Y_y, A_a$$

$O_i$  – new coordinate system;  
 $X_x$  – coordinates of center;  
 $A_a$  – rotation angle.

- Assignment of a new coordinate system by indicating an identifier of the earlier defined point, in which the center is located, and by the rotation angle relatively the primal system.

Format:

---

$$O_i = P_j, A\alpha$$

---

$P_j$ —point of the center

## 1.2 POINT ASSIGNMENT

### 1.2.1 Point assignment by rectangular coordinates

- Point assignment by coordinates in the primal system

Format:

$$P_i = X_x, Y_y$$

- Determination of a point by coordinates in the defined system, different from the primal.

Format:

$$P_i = X_x, Y_y, O_i$$

## 1.2.2 Point assignment by polar coordinates

### ■ Relatively the beginning of coordinates

Format:

$$P_i = Mm, Aa$$

$Mm$  – length of a vector, which connects the defined point with the beginning of coordinates

$Aa$  – an angle between a vector and the positive direction of the “X” axis

### ■ Relatively the point defined earlier

Format:

$$P_i = Mm, Aa, P_j$$

$Mm$  – length of a vector connecting the defined point and the earlier defined point

$Aa$  – an angle between a vector and the positive direction of the “X” axis

$P_j$  – the earlier defined point

■ In the relative coordinate system

Format:

$$P_j = M_m, A_a, O_i$$

$M_m$  – length of a vector connecting the defined point and the earlier defined point

$A_a$  – an angle between a vector and the positive direction of the “X” axis

$O_i$  – the earlier defined coordinate system

**1.2.3 Point assignment by increment of coordinates relatively the earlier defined point**

Format:

$$P_i = P_j, X_x, Y_y$$

$P_j$  – the earlier defined point

$X_x, Y_y$  – transition by X and Y coordinates accordingly

### 1.2.4 Point assignment by intersection of two lines

Format:

$$P_i = L_i, L_k$$

$L_i$  and  $L_k$  – earlier defined lines

### 1.2.5 Point, defined by polar coordinates relatively the earlier defined point

Format:

$$P_i = P_j, P_k, A\alpha$$

$P_j$  – the earlier defined point

$P_k$  – a point, the distance to which from the  $P_j$  point is the length of a vector

$A\alpha$  – an angle between vectors and the positive direction of the “X” system

Example:

for  $i=3$  to 12 do  $p.i=p[0,0], p[-60,0], a(i*10)$

### 1.2.6 Point, as the center of the earlier defined circle

Format:

$$P_i = C_j$$

### 1.2.7 Point assignment by intersection of a line and a circle

A line and a circle usually intersect in two points. In order to determine the number of a point of intersection, it is necessary to look along a line at that direction, at which the line enters into the point assignment operator. Thus, one of point can be selected by indicating a corresponding sign of a line in the point assignment operator. Positive direction of a line accepts in the operator as default. To indicate a negative direction it is necessary to put the “-” symbol before the identifier of a line.

Format:

$$P_i = L_j, C_k$$

$L_j$  – the earlier defined line

$C_k$  – the earlier defined circle

### 1.2.8 Point assignment by intersection of two circles

Two circles, usually intersects in two points. In order to select a required point, it is necessary to define a number of an intersection. To do so, connect in one’s mind centers of circles of a line (auxillary line), direct view along this line in direction coinciding with the order of indicating of circles in the operator, i.e. from the first indicated circle to the second. The being assigned point will be located on the left. Thus, the order of recording of circles in the point assignment operator defines by locating of centers of circles on the auxillary line.

Format:

$$P_i = C_j, C_k$$

---

$C_j$  and  $C_k$  – earlier defined circles

---

### 1.2.9 Assignment of a point of the axial symmetry

This method allows to define a point, located symmetrically to the earlier defined point relatively an arbitrary defined line, coinciding with one of coordinate axes.

- A point symmetrical to the present point relatively an arbitrary line.

Format:

$$P_i = P_j, L_k \langle \text{parameters} \rangle$$

---

$P_j$  – the earlier defined point

$L_k$  – the earlier defined line

- A point symmetrical to the present point relatively one of coordinte axes

Formats:

$$P_i = P_j, LX$$

$$P_i = P_j, LY$$

LX – the axis “X” of the primal coordinate system

LY – the axis “Y” of the primal coordinate system

### 1.2.10 Point assignment by transition to a new coordinate system

Two possible ways:

- A being assigned point is located in a new coordinate system likewise the initial point in the primal

Format:

$$P_i = O_i, P_k$$

Pj – the earlier defined point

Oi – the earlier defined coordinate system

- A being assigned point is located in a new coordinate system likewise the initial point in the indicated defined system

Format:

$$P_i = O_j, P_k, O_n$$

$O_i$  – the system where the assigned point is located

$O_n$  – the system where the initial point is located

### 1.2.11 Point assignment, lying on a circle under the defined central angle

Format:

$$P_i = C_i, A\alpha$$

$C$  – the earlier defined circle

$A\alpha$  – an angle of a vector, connecting the center of a circle and the defined point

### 1.2.12 Point, defined by one of coordinates and lying on a line

#### ■ With the defined "X" coordinate

Format:

$$P_i = X_x, L_i$$

$X_x$  - a "X" coordinate

$L_i$  - the earlier defined line

#### ■ With the defined "Y" coordinate

Format:

$$P_i = Y_y, L_i$$

$Y_y$  - an "Y" coordinate

$L_i$  - the earlier defined line

### 1.2.13 Assignment of a point, lying on a line at distance from the earlier defined point

Format:

$$P_i = L_j, M_m, P_k$$

$L_j$  – the earlier defined line

$M_m$  – distance

$P_k$  – the earlier defined point

### 1.2.14 Point, as the nodal point of a contour

An operator allows to define a point, as a point of intersection of two consequent elements of contour

Format:

$$P_i = K_j, N_n$$

$K_j$  – the earlier defined contour

$N_n$  – number of a point in the contour

### 1.2.15 Point, defined by intersection of a line and a contour

To select one point from the points of intersection, One should indicate the number of a sought point in direction of a line. When counting points of intersection, it is necessary to consider the following rules:

- If one of sections of a contour belongs to a line, then points of intersection are the first and the final points of the section
- If a line passes through the point of intersection of two adjoining elements of a contour, then only one point is counted
- If a line passes through a point of intersection of two not adjoining elements of a contour, then both points are counted

Format:

$$P_i = K_j, L_t, N_n$$

$K_j$  – the defined contour

$L_t$  – the earlier defined line

$N_n$  – number of point of intersection

$$P_i = K_j, L_t, N_2$$

### 1.2.16 Point, defined by intersection of a circle and a contour

To select one of points of intersection One should indicate the number of a sought point in rounding a counter. When counting points of intersection it is necessary to consider the following rules:

- If one of arcs of contour belongs to a circle, then points of intersection are the first and the final points of the arc
- If a circle passes through a point of intersection of two adjoining elements of a contour, then only one point is counted
- If a circle passes through a point of intersection of two not adjoining elements of a contour, then both points are counted

Format:

$$P_i = K_j, C_t, N_n$$

$C_t$  – the defined circle

### 1.2.17 Point, defined by intersection of two contours

To select one of points of intersection one should indicate the number of sought point in rounding by first of defined contours. When counting points of intersection it is necessary to consider the following rules:

- If one of elements of a contour belongs, coincides or overlaps with an element of another contour, points of intersection are the first and the final points of elements, belonging to both contours.
- If an element passes through the point of intersection of two adjoining elements of another contour, then one point is counted
- If an element passes through the point of intersection of two not adjoining elements of another contour, then two points are counted.

Format:

$$P_i = K_j, K_t, N_n$$

$K_j, K_t$  – defined contours

$N_n$  – number of a point of intersection

### 1.2.19 Touch point of two contours in transition of one of them towards the indicated direction until collision with the second

Format:

$$P_i = K_j, K_k, A_a$$

$K_j, K_k$  - the earlier defined contours

$A_a$  – an angle of direction of a contour transition  $K_j$

### 1.2.20 Point, laying on a contour at the indicated distance along a contour from the earlier defined point

Format:

$$P(i) = K(k), P(j), M_m$$

$m$  – a distance along a contour from the  $P_j$  point

in negative sense – the distance against the direction of a contour

### 1.2.21 Point scaling

Format:

$$P_i = P_j, P_k, M_m$$

$P_j$  – the initial point

$P_k$  – a point of the center of scaling

$M_m$  – a scaled coefficient

Example:

$$p_1 = p_2[0,0], p_3[20,0], m_5$$

**1.2.22 Projection of a point on a circle**

Format:

---

 $P_i = P_j, C_k$ 

---

$P_j$  – the initial point

$C_k$  – a circle on which point  $P_j$  is projected

If before “ $C_k$ ” there is the sign “-”, then the furthest point will be found, otherwise – closest.

## 1.3 LINE ASSIGNMENT

### 1.3.1 Line passing through two points defined earlier

Format:

$$L_i = P_i, P_k$$

$P_i, P_k$  – earlier defined points

### 1.3.2 Line passing through a point under the defined angle

If an identifier of the “A” angle enters an operator with the “-” symbol, then the angle counts out clockwise.

- A line passing through a point under the defined angle to the “X” axis

Format:

$$L_i = P_i, A\alpha$$

$A\alpha$  – an angle between the defined point and the “X” axis

$P_i$  – the earlier defined point

- A line passing through a point, defined by coordinates under the defined angle to the "X" axis, in the relative coordinate system

Format:

$$L_i = X_x, Y_y, A_a, O_k$$

$O_k$  – a coordinate system defined earlier

$X_x, Y_y$  – coordinates of a point in the "Ok" system

$A_a$  – an angle between the defined line and the "X" axis of the "Ok" coordinate system

If in an operator instead of coordinates one enters the earlier defined point, then definitions of its coordinates will be interpreted in the "Ok" system

### 1.3.3 Line passing through a point, tangent to the defined circle

Usually only two lines pass through a point and are tangent to a circle. In order to select one of them, it is necessary to define with which sign the identifier of the circle should enter an operator. Sign "+" is not compulsory. A circle has the sign "+" if in the point of touching with a line, the positive direction of a circle coincides with direction of the line. At that, the direction of the line is from the first element to the second.

A circle has "-" sign, if in the point of touching with the defined line directions are diverse.

Formats:

$$Li = Pj, Ck$$

$$Li = Ck, Pj$$

$Pj$  – the defined point

$Ck$  – the defined circle

### 1.3.4 Line tangent to a circle under the defined angle

Two lines tangent to a circle under the defined angle are possible. To select one of them it is necessary to define the sign of the circle, analogically to the previous paragraph.

Format:

$$Li = Cj, Aa$$

$Cj$  – the earlier defined circle

$Aa$  – an angle between the positive direction of the "X" axis and the defined line

### 1.3.5 Assignment of a line tangent to two circles

Usually, exist only four lines tangent to two circles. Selection of one of them can be done by specification of signs of circles and the order of their inclusion into an operator. To define the order of specification of circles in the operator, it is necessary to look along the positive direction of a line. The order of touch points corresponds to the order of specification of circles in the operator.

Format:

$$L_i = C_j, C_k$$

$C_j, C_k$  – earlier defined circles

### 1.3.6 Assignment of a line parallel to the given one

The “M” parameter is the distance between lines. “M” is positive, if a being defined line is on the left from the initial line, in coincidence of a view and the direction of a line. “M” is negative, if a being defined line is on the right from the initial line, in coincidence of a view and the direction of a line.

- A line, parallel to one of coordinate axes, passing to the defined distance from the axis.

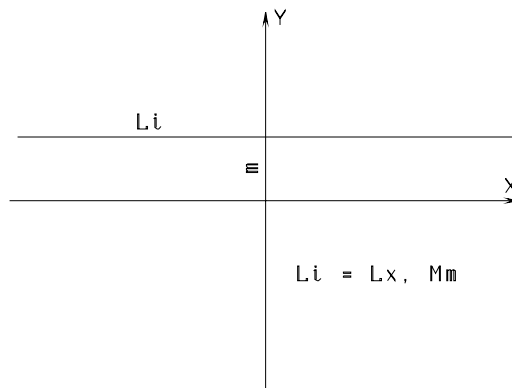

$$L_i = L_x, M_m$$

$$L_i = L_y, M_m$$

$L_x$  – the “X” axis of the primal coordinate system

$L_y$  – the “Y” axis of the primal coordinate system

$M_m$  – the distance

■ A line, parallel to an arbitrary defined plane, passing to the defined distance

Format:

$$Li = Lj, Mm$$

$Lj$  – the earlier defined line

**1.3.7 Line tangent to a contour under the defined angle**

Two lines, tangent to a contour under the defined angle are possible. To select one of them it is necessary to define the sign of a contour in the operator.

The sign is positive, if a being defined line is on the left from a contour, in coincidence of a view and a positively directed being defined line

The sign is negative, if a being defined line is on the right from a contour, in coincidence of a view and a positively directed being defined line.

Format:

$$Li = Kj, A\alpha$$

$Kj$  – the earlier defined contour

$A\alpha$  – an angle between the positive direction of the “X” axis and the defined line.

**1.3.8 Line passing through a point and tangent to a contour**

Two lines passing through a point and tangent to a contour are possible. To select one of them it is necessary to define a sign of a contour in the operator.

The sign is positive, if a being defined line is on the left from a contour, when looking from a point to the contour.

The sign is negative, if a being defined line is on the right from a contour, when looking from a point to the contour.

Format:

$$Li = Pk, Kj$$

$Kj$  – the earlier defined contour

$Pk$  – the earlier defined point

**1.3.9 Line as an element of the earlier defined contour**

Format:

$$Li = Kj, Nn$$

$Kj$  – the earlier defined contour

$Nn$  – a contour element number

### 1.3.10 Line defined by coefficients of a normal equation of a line

Format:

$$Li = a, b, c$$

a, b, c – coefficients of a normal equalization of a line

### 1.3.11 Transition of a line

Format:

$$Li=Lj, Xx, Yy$$

Lj – the earlier defined line

Xx, Yy – displacement by X and Y coordinates

Example:

$$l2=l1[-0.7, 0.5, 10], X50, Y20$$

### 1.3.12 Rotation of a line around a point to the defined angle

Format:

$$Li=Lj, Pk, Aa$$

Lj – the initial circle

Pk – the center of rotation

Aa – an angle of rotation

Example:

$$l1=l3[ly, m0], p1[0, 0], a20$$

$$l2=l4[lx, m0], p1, a4$$

### 1.3.13 Line scaling

Format:

$$Li=Lj, Pk, Mm$$

Lj – the initial circle

Pk – a point of the center of scaling

Mm – a scaled coefficient

**Example:**

$l1=l3[lx,m50],p1[0,0],m2$   
 $l2=l4[ly,m50],p1,m0.5$

## 1.4 CIRCLE ASSIGNMENT

---

### 1.4.1 Circle, defined by a center and a radius

- A circle defined by coordinates of a center and a radius

Format:

---

$$Ci = Xx, Yy, Rr$$

---

$Xx, Yy$  – coordinates of a center

$Rr$  – a radius

- A circle defined by a point and a radius

Format:

---

$$Ci = Pj, Rr$$

---

$Pj$  – the earlier defined point

### 1.4.2 Circle, symmetrical to the initial circle relatively a line

Format:

$$C_i = C_j, L_k$$

$C_j$  – the earlier defined circle

$L_k$  – the earlier defined line

### 1.4.3 Circle, defined by displacement of the initial circle

Format:

$$C_i = C_j, M_m, A_a$$

$C_j$  – the earlier defined circle

$M_m$  – length of the transference vector

$A_a$  – an angle of the transference vector

### 1.4.4 Circle with the defined center, tangent to a line

Formats:

$$C_i = P_j, L_k$$

$$C_i = X_x, Y_y, L_k$$

$P_j$  – the earlier defined point

$L_k$  – the earlier defined line

$X_x, Y_y$  – point coordinates

### 1.4.5 Circle with the defined center, tangent to another circle

Usually, exist only two of such circles. In the present variant, a being defined circle has external touch with an earlier assigned, in another – internal. To select the external touch it is necessary to define the “-“ sign for the initial circle in the operator.

Format:

$$C_i = P_j, C_k$$

$C_k$  – the earlier defined circle

$P_j$  – the earlier defined point

1.4.6 Circle of the defined radius, tangent to two lines

The order of recording of lines is not important. Signs of lines in the circle-defining operator are the indications of coincidence or not coincidence of direction of a line and a being defined circle in the touch point. If in the touch point directions do not coincide, then the line has the “-“ sign.

Format:

$$C_i = L_j, L_k, R_r$$

$L_j, L_k$  – defined lines

1.4.7 Circle of the defined radius, tangent to two circles

To select a required variant it is necessary to define in the operator the order of assignment of the initial circles, and its signs. The order defines as follows:

- Centers of the initial circles, in one’s mind are connected with a line
- Direction of a view along the line must be selected in such a way, so that the center of a being defined circle is on the right
- The order of indication of circles in the operator must coincide with the order of disposition of centers of those circles on the line.

Signs, with which the initial circles enter the operator, indicate on coincidence or not coincidence of directions in the touch point with a being defined circle. In not coincidence of directions, a circle enters the operator with the “-“ sign.

Format:

$$C_i = C_j, C_k, R_r$$

$C_i, C_k$  – earlier defined circles

### 1.4.8 Circle of the defined radius, tangent to the earlier defined line and circle

To define the order of recording of elements in the operator, it is necessary do the following;

- Imagine a line as an arc of a circle with an endless radius with a center on the left from the line. (a view must coincide with the positive direction of the line)
- In one's mind connect by a segment the center of the imagined arc with the center of the defined circle
- Direction of a view on the section should be chosen in such a way, so that the being defined circle is on the left

The order of recording of elements in the operator must correspond to dislocation of centers of the initial elements on the imagined section in the direction of a view.

Definition of a sign of a line (reference in the paragraph "Circle of the defined radius, tangent to two lines"), sign of a circle (reference in the paragraph "Circle of the defined radius, tangent to two circles").

Formats:

$$C_i = L_j, C_k, R_r$$

$$C_i = C_k, L_j, R_r$$

$C_k$  – the earlier defined circle

$L_j$  – the earlier defined line

- $C_1 = -C_k, L_j, R_r$
- $C_2 = C_k, L_j, R_r$
- $C_3 = -C_k, -L_j, R_r$
- $C_4 = C_k, -L_j, R_r$
- $C_5 = L_j, C_k, R_r$
- $C_6 = L_j, -C_k, R_r$
- $C_7 = -L_j, C_k, R_r$
- $C_8 = -L_j, -C_k, R_r$

### 1.4.9 Circle of the defined radius, passing through a point and tangent to a line

To define the order of recording of elements in the operator, it is necessary do the following;

- Imagine a line as an arc of a circle with an endless radius with a center on the left from the line. (a view must coincide with the positive direction of the line)
- In one's mind connect by a segment the center of the imagined arc with the center of the defined circle
- Direction of a view on the section should be chosen in such a way, so that the center of the being defined circle is on the left

The order of recording of elements in the operator must correspond to the sequence of their dislocation on the imagined section

The rule of defining of a sign of a line (reference in the paragraph "Circle of the defined radius, tangent to two lines").

Formats:

$$C_i = P_j, L_k, R_r$$

$$C_i = L_k, P_j, R_r$$

$P_j$  – the earlier defined point

$L_k$  – the earlier defined line

### 1.4.10 Circle of the defined radius, passing through a point and tangent to a circle

To define the order of recording of elements, it is necessary do the following;

- In one's mind connect by a section the center of the initial circle and a point
- Direction of a view on the section should be chosen in such a way, so that the center of the being assigned circle is on the left.

The order of recording of elements in the operator must correspond to the sequence of their dislocation on the imagined section

Formats:

$$C_i = P_j, C_k, R_r$$

$$C_i = C_k, P_j, R_r$$

$P_j$  – the earlier defined point  
 $C_k$  – the earlier defined circle

### 1.4.11 Circle of the defined radius, passing through two points

To define the order of recording of elements in the operator, it is necessary do the following;

- Connect the initial points by a section
- Direction of a view on the section should be chosen in such a way, so that the center of the being assigned circle is on the left.

The order of recording of elements in the operator must correspond to the sequence of their dislocation on the imagined section

Format:

$$C_i = P_j, P_k, R_r$$

$P_j, P_k$  – earlier defined points

### 1.4.12 Circle, concentric to the present circle

The “M” parameter is a difference of radiuses of the initial circle and an assigned. “M” is positive, if the initial circle is internal relatively the assigned. “M” is negative, if the initial circle is external relatively the assigned.

Format:

$$C_i = C_j, M_m$$

$C_j$  – the earlier defined circle

### 1.4.13 Circle with a center in the defined point and tangent to a contour

If an identifier of a contour enters the operator with the sign “+”, then the touch is internal, otherwise – external.

Format:

$$C_i = P_j, K_k$$

$P_j$  - the earlier defined point

$K_k$  - the earlier defined contour

**1.4.14 Circle, as an element of the earlier defined contour**

Format:

$$C_i = K_j, N_n$$

$K_j$  - the earlier defined contour

$N_n$  – a number of the contour's element

**1.4.15 Rotation of a circle around a point to the defined angle**

Format:

$$C_i = C_j, P_k, A_a$$

$C_j$  – the initial circle

$P_k$  – the center of rotation

$A_a$  – an angle of rotation

Example:

$$c1=c3[0,40,30],p1[0,0],a20$$

$$c2=c4[60,0,50],p1,a40$$

**1.4.16 Circle scaling**

Format:

$$C_i = C_j, P_k, M_m$$

$C_j$  – the initial circle

$P_k$  – the point of the center of scaling

$M_m$  – scaling coefficient

Example:

$$c1=c3[50,0,30],p1[0,0],m0.5$$

$$c2=c4[0,50,20],p1,m2$$

## 1.5 CIRCLE, DEFINED FROM THE CONDITION OF THREE CONTACTS

To select one of possible circles it is necessary to define correctly signs of parameters (if they are not points) and their sequence.

Definition of a sign of a line (ref. in the paragraph "Circle of the defined radius, tangent to two lines") and sign of a circle (ref. in the paragraph "Circle of the defined radius, tangent to two circles").

To select the correct sequence of parameters in the operator it is necessary to enumerate them, starting from anyone, in the order of their contact with a being defined circle in rounding counter-clockwise.

### 1.5.1 Circle, passing through two points and tangent to the present circle

Formats:

$$C_i = P_j, P_k, C_n$$

$$C_i = P_j, C_n, P_k$$

$$C_i = C_n, P_j, P_k$$

$P_j, P_k$  – earlier defined points

$C_n$  – the earlier defined circle

### 1.5.2 Circle, passing through two points and tangent to the present line

Formats:

$$C_i = P_j, P_k, L_n$$

$$C_i = P_j, L_n, P_k$$

$$C_i = L_n, P_j, P_k$$

$P_j, P_k$  – earlier defined points

$L_n$  – the earlier defined line

### 1.5.3 Circle, passing through one point and tangent to two lines

Formats:

$$C_i = P_j, L_k, L_n$$

$$C_i = L_k, P_j, L_n$$

$$C_i = L_k, L_n, P_j$$

$P_j$  – the earlier defined point

$L_k, L_n$  - earlier defined lines

**1.5.4 Circle, passing through one point and tangent to two circles**

Formats:

$$C_i = P_j, C_k, C_n$$

$$C_i = C_k, P_j, C_n$$

$$C_i = C_k, C_n, P_j$$

$P_j$  – the earlier defined point

$C_k, C_n$  – earlier defined circles

**1.5.5 Circle, passing through one point and tangent to a line and a circle**

Formats:

$$C_i = P_j, C_k, L_n$$

$$C_i = C_k, P_j, L_n$$

$$C_i = C_k, L_n, P_j$$

$$C_i = P_j, L_n, C_k$$

$$C_i = L_n, P_j, C_k$$

$P_j$  – the earlier defined point

$C_k$  – the earlier defined circle

$L_n$  – the earlier defined line

### 1.5.6 Circle, tangent to two circles and a line

Formats:

$$C_i = C_j, C_k, L_n$$

$$C_i = C_j, L_n, C_k$$

$$C_i = L_n, C_j, C_k$$

$C_j, C_k$  – earlier defined circles

$L_n$  – the earlier defined line

### 1.5.7 Circle, tangent to two lines and a circle

Formats:

$$C_i = C_j, L_k, L_n$$

$$C_i = L_k, C_j, L_n$$

$$C_i = L_k, L_n, C_j$$

$C_j$  – the earlier defined circle

$L_k, L_n$  - earlier defined lines

### 1.5.8 Circle, passing through three points

Format:

$$C_i = P_j, P_k, P_n$$

$P_j, P_k, P_n$  – earlier defined points

### 1.5.9 Circle, tangent to three lines

Format:

$$C_i = L_j, L_k, L_n$$

$L_j, L_k, L_n$  – earlier defined lines

### 1.5.10 Circle, tangent to three circles

Formats:

$$C_i = C_j, C_k, C_n$$

$$C_i = C_j, C_k, C_n, N2$$

$C_j, C_k, C_n$  – earlier defined circles

There is a possible case, at which indicated conditions for selection of one of circles is not enough. For selection of the internal circle it is necessary to indicate the modifier #2

## 1.6 CONTOUR

---

### 1.6.1 Conception of a contour

A contour in geometrical processor is a joining of segments of geometrical elements. An assignation operator in the left part, contains identifier of a contour – “K”, with the contour’s number. In the right part – a list of parameters in accordance with one of acceptable methods of assignation.

For a contour exists a definition called direction of rounding. Thus, a contour described as :

$$K1 = P10, L1, -C10, -L12, P3$$

and contour:

$$K2 = P3, L12, C10, -L1, P10$$

have opposite directions of rounding.

The amount of simultaneously defined contours is limited only by the RAM capabilities (for every contour, in the RAM stores the adress of the begining and the adress of the ending of a contour in the file GPS.DAT)

Re-definition of used contours, by means of conferring to an identifier a new meaning is possible.

Accepts usage of the earlier defined contour and re-definition of a contour with the similar identifier within one operator.

Example:

$$K10 = K10, M5$$

### 1.6.2 Formation of a contour from the defined geometrical elements

#### ■ Operator creation

At that method of assigning the right part of an operator contains enumeration of elements of a contour in such sequence, in which they penetrate into it. Description of a contour begins from a point, laying on the first element (circle or a line) and finishes by a point, laying on the last element.

In order to describe a contour it is necessary to previously define all its elements (otherwise enclosed operators of definition of this elements must be as parameters), except for radiuses of rounding, which could be defined directly in the contour definition operator (i.e. without corresponding circle).

If in a contour exists intersection of a line and a circle, then one should define a number of intersection point, at which it is necessary to perform a transition from one element to another. To do so, one should look along a line in direction with which it enters a contour. The first point of transition sets as default. To define the second point it is necessary to define the modifier #2.

If in an operator exists intersections of two circles, the one should define the number of intersection point at which it is necessary to perform a transition from one circle to another. To do so, one should look along a line connecting centers of the circles in direction from the first circle to the second. The first point at that, will be on the left. The first point of transition sets as default. To define the second point it is necessary to define modifier #2.

The first and the last points can be left undefined in the operator of contour assignment. In this case, the first point will be the point of intersection of two initial elements, and the last point will be the point of intersection of two final elements of a contour.

**Example:**

K23 = P1, -L2, N2, C7, P12

### 1.6.3 Rounding radius

The rounding radius is an arc of a circle, conjugating intersecting geometrical elements. Identifier, pointing on the presence of rounding, inserts into a contour assignment operator between identifiers of conjugating elements. At that, it is necessary to conceder the sign, with which an arc enters a contour.

If for conjugated elements assigned a number of intersection point, then identifier of rounding inserts after the "N" parameter.

**Example:**

K10 = P6, L8, -R20, L10, P1

## 1.7 CONTOUR, DEFINED BY MULTITUDE OF POINTS

### 1.7.1 Contour – broken line

The right part of the contour assignment operator contains enumeration of points at that sequence, at which they should be connected by segments.

Formar:

$$K_i = P_j, P_k, \dots, P_n$$

### 1.7.2 Spline

The first parameter in an operator is the “M” identifier, which indicates the magnitude of deviation at approximation by spline sections – broken line. After that follows the initial condition (line or circle), then enumeration of points at that sequence, at which they should be connected at spline interpolation – broken line. The operator finishes by definition of condition on the end of spline - broken line (line or circle).

The first point must lie on the element, defining initial condition

The last point must lie on the element, defining final condition

Format:

$$K_i = M_m, L_t, P_j, P_k, \dots, P_n, L_q$$

$$K_i = M_m, C_t, P_j, P_k, \dots, P_n, L_q$$

$$K_i = M_m, C_t, P_j, P_k, \dots, P_n, C_q$$

$$K_i = M_m, L_t, P_j, P_k, \dots, P_n, C_q$$

$$K_1 = M_0, L_1, -L_1, P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8, P_1, -L_1$$

### 1.7.3 Approximation by arcs

This method of assignment allows to define on a multitude of points a smooth contour, elements of which are tangent arcs. There is a possible case then in the initial data three points, laying on one line are defined one after one. Then, corresponding arc will degenerate into a section of a line.

The first parameter in the operator is the identifier of geometrical an element (line or circle), defining the initial condition. Further follows enumeration of points in that sequence, in which they should be connected be arcs in approximation.

Formats:

$$K_i = Lt, P_j, P_k, \dots, P_n$$

$$K_i = Ct, P_j, P_k, \dots, P_n$$

$$K_1 = L1, P1, P4, P6, P7, P5, P2, P3, P1$$

### 1.7.4 Spiral of Archimed

Format:

$$K_i = Mm, P_i, P_j, P_k$$

$Mm$  – magnitude of deviation of the defined contour from theoretical spiral of Archimed; at that a sign in operanda assigns direction of a spiral

$P_i$  – point of the center of a spiral

$P_j$  – the initial point

$P_k$  – the final point of a spiral

## 1.8 MODIFICATION OF A CONTOUR

Geometrical processor allows to assign contours, as modification of earlier defined contours. This feature includes the following means:

- Parallel transfer
- Transfer – rotation
- Transfer in relative coordinate system
- Assignment of a contour of an axial symmetry
- Creation of an equidistant contour
- Multiple rotation with joining
- Multiple transfer with joining
- Contour defined by transfer of the initial contour to defined direction until collision with another contour
- Change of direction of rounding
- Joining of contours
- Selection of a contour, as a sub-multitude of earlier defined contour

### 1.8.1 Parallel transfer

Definition of a contour by parallel transfer of the earlier defined contour can be done by two methods:

- **Assignment of parallel transfer by transferences along the "X" and "Y" axes of the initial contour**

Format:

$$K_i = K_j, X_x, Y_y$$

$X_x$  – transference by the "X" axis

$Y_y$  – transference by the "Y" axis

### ■ Assignment of parallel transfer by a vector

Format:

$$K_i = K_j, A_a, M_m$$

$M_m$  – length of a transition vector

$A_a$  – an angle between the positive and negative directions of the “X” axis and a vector

### 1.8.2 Transfer – rotation

To define a contour by transfer – rotation of an assigned contour enters a definition of a point of rotation center. Transformation can be presented as the following sequence of actions:

- Rotation of the initial contour around the point of rotation center
- Parallel transfer of a turned contour

Parallel transfer of turned contour assigns by combining of a point of rotation center with the defined point

Format:

$$K_i = K_j, P_k, P_n, A_a$$

$K_j$  – the initial contour

$P_k$  – point of rotation center

$P_n$  – a point, with which “ $P_k$ ” combines for creation of transfer

$A_a$  – a rotation angle

### 1.8.4 Transfer of a contour to the relative coordinate system

Assigning of a contour by the transfer of the initial contour into another coordinate system basically has the following formula: a being assigned contour located in defined coordinate system is the same, as the initial contour located in the initial coordinate system.

- **Assigning of a contour by transfer of the initial contour from the primal system to the relative**

Format:

---

$$K_i = O_j, K_k$$

---

$O_i$  – the earlier defined relative coordinate system

- **Assigning of a contour by transfer of the initial contour from one relative coordinate system, to another**

Format:

---

$$K_i = O_j, K_k, O_n$$

---

$O_j$  – a relative coordinate system, into which a assigned contour is to be located

$K_k$  – the initial contour

$O_n$  – a relative coordinate system, in which locates the initial contour

### 1.8.4 Assignment of a contour by the axial symmetry

Axial symmetry allows to define a contour symmetrical to the present relatively an arbitral line. At that, at the defined contour changes direction of rounding relatively to the initial contour.

#### ■ Symmetry relatively one of axes of the primal coordinate system

Format:

$$K_i = K_j, L_x$$

$$K_i = K_j, L_y$$

$L_x$  – the “X” axis

$L_y$  – the “Y” axis

#### ■ Symmetry relatively an arbitral line

Format:

$$K_i = K_j, L_k$$

$L_k$  – the defined line

### 1.8.5 Creation of an equidistant contour

This method allows to define contour, equidistant to the initial contour

Format:

$$K_i = K_j, M_m \{, ANG a\}$$

$M_m$  – a value of equidistant

$a$  – an angle of rounding

If an angle between neighbouring elements is less than “ $a$ ”, then adds an arc of rounding

### 1.8.6 Multiple rotation with joining

Creation of a contour by this method can be presented as:

- Multiple rotation of the initial contour round the point of rotation center by such a method, so that the initial point of every following contour coincides with the final point of the previous.
- Joining of all obtained by rotation contours into the resulting contour

The initial contour is a segment of the defined. The centre of rotation is defined by a point. For correct assigning it is necessary to accomplish the following conditions:

- The initial point of contour, final point of contour and the point of rotation center must not coincide

- The initial and final points of the initial contour must be equally distanced from the point of rotation center

Format:

$$K_i = K_j, P_k, N_n$$

$P_k$  – the defined point, the center of rotation

$N_n$  – number of rotations

### 1.8.7 Multiple transfer with joining

Creation of a contour by this method can be presented as follows:

- Multiple parallel transfer of the initial contour by such a method, so that the initial point of every following transferred contour coincide with the final of a previous.
- Joining of all obtained by transfer contours into the resulting contour

The initial contour is a segment of defined. For correct assigning it is necessary to accomplish the following condition: the initial and the final points of the initial contour must not coincide

Format:

$$K_i = K_j, N_n$$

$N_n$  – number of transfers

### 1.8.8 Contour defined by transfer of the initial contour to the defined direction up to the collision with another one

Format:

$$K_i = K_j, K_k, A_a$$

$K_j$  – the initial contour

$K_k$  – the earlier defined contour

$A_a$  – an angle of transfer direction of the initial contour

### 1.8.9 Change of a direction of rounding

This method allows to assign a contour, coinciding with the initial and possessing of opposite direction of rounding

Format:

$$K_i = - K_j$$

If sign "-" is not defined, then a being defined contour will be identical to the initial.

### 1.8.10 Joining of contours

This method allows to assign a contour , as a joining of earlier described contours

Format:

$$K_i = K_j, K_k, \dots, K_n$$

For correct assigning it is necessary to accomplish the following condition: the final point of every previous contour must coincide with the initial point of every following contour. At a necessity, parameters of connection of being unified by arcs contours:  $K_i = K_j, R_r, K_k, R_s, \dots, K_n$ , can be defined in an operator.

### 1.8.11 Contour defined by scaling of the initial contour

Format:

$$K_i = K_j, P_k, M_m$$

$K_j$  – the initial contour

$P_k$  – the point of center of scaling

$M_m$  – scaling coefficient

### 1.8.12 Selection of a contour, as a sub-multitude of the initial contour

#### ■ Selection of a sub-contour by numbers of elements

Format:

$$K_i = K_j, N_n, N_m$$

$N_n$  – number of the initial element

$N_m$  – number of the final element

#### ■ Selection of a sub-contour between two arbitral points, lying on the initial contour

Format:

$$K_i = K_j, P_k, P_l$$

$K_j$  – the initial contour

$P_k, P_l$  – the initial and the final points of a being selected contour

### 1.8.13 Rounding in the nodal point of the initial contour

Format:

$$K_i = K_j, N_n, R_r$$

$K_j$  - the initial contour

$N_n$  – number of a nodal point

$R_r$  – radius of rounding

Example:

$$k_1 = p[0,0], p[40,0], p[40,-50], p[-40,-50], p[-40,-70]$$

$$k_2 = k_1, n(2), r(10)$$

## 1.9 GEOMETRICAL FUNCTIONS

Geometrical functions are meant for transformation of geometrical data types into real data types. In the language of a dialogue monitor with a fully loaded geometrical process, it is allowed to use geometrical functions equally to the standard mathematical ones. (reference: description of the language of a dialogue monitor of the SPRUT package).

### 1.9.1 Functions of transformation of geometrical elements parameters into real data types

- 1)  $X[P_i]$  - coordinate "X" of point  $P_i$ ;
- 2)  $Y[P_i]$  - coordinate "Y" of point  $P_i$ ;
- 3)  $X[C_i]$  - coordinate "X" of circle center  $C_i$ ;
- 4)  $Y[C_i]$  - coordinate "Y" of circle center  $C_i$ ;
- 5)  $R[C_i]$  - radius of circle  $C_i$ ;
- 6)  $A[L_i]$  - an angle between the positive direction of the "X" axis and the line  $L_i$ ;

### 1.9.2 Functions of transformation of geometrical elements' mutual location parameters into the real data types

- 1)  $A[L_i, L_k]$  – angle between the lines  $L_i$  and  $L_k$ ;
- 2)  $A[P_i]$  – central angle of a point (a slope angle of a line, connecting the beginning of a coordinate system with the point  $P_i$ );
- 3)  $A[P_i, P_k]$  – slope angle of a line, connecting the points  $P_i, P_k$ ;
- 4)  $M[P_i, P_k]$  – distance between the points  $P_i$  and  $P_k$ ;
- 5)  $M[P_i, L_k]$  – shortest distance between the line  $L_k$  and the point  $P_i$ ;
- 6)  $M[L_i, L_k]$  – shortest distance between the lines  $L_i$  и  $L_k$ ;
- 7)  $M[L_i, C_k]$  – shortest distance between the line  $L_i$  and circle  $C_k$ ;
- 8)  $M[P_i, C_k]$  – shortest distance between the point and circle  $P_i C_k$ ;
- 9)  $M[C_i, C_k]$  – shortest distance between the circles  $C_i$  и  $C_k$ ;
- 10)  $M[P_i, K_j]$  – shortest distance between the point  $P_i$  and contour  $K_j$ ;
- 11)  $M[K_i, P_j, P_k]$  – length of a part of the contour  $K_i$ , located between the points  $P_j$  и  $P_k$ ;
- 12)  $M[K_i, K_j, A_a]$  – distance between the contours  $K_i$  и  $K_j$  in the direction  $A_a$ ;

### 1.9.3 Functions of calculation of the ortogonal distance between two points by axes "X" and "Y"

Distance has a sign corresponding to the direction from the first point to the second

Format:

$X[P_i, P_j]$ ,	$Y[P_i, P_j]$ ,
$X[P_i, C_j]$ ,	$Y[P_i, C_j]$ ,
$X[C_i, C_j]$ ,	$Y[C_i, C_j]$

Example:

```
p1=100,100
p2=-100,-100
c1=x50,y0,r50
c2=x-50,y0,r30
xPP=X[p1,p2]
yPP=Y[p1,p2]
xPC=X[c1,p1]
yPC=Y[p1,c1]
